

Facial recognition technology has really in my opinion become somewhat of a staple along with other dominant variables when it comes to the display of advancements of tech. Facial recognition has actually been around for approximately decades but has a subtle continuum of gaining widespread adoption from many places around the world. There are essentially three components that facial recognition technology follows/abides by detection, analysis and recognition. First your face is captured through either a photo or video the software within then measures a vast amount of facial features called either landmarks or nodal points on the face to simplify it a little more when it come to this specific aspect the nodal and or landmark is essentially taking in measurements of ones face and collecting a total of 80 different measurements. Immediately following after measurements are taken it is then converted into creating a mathematical formula which is then created in order to create your unique facial signature. This technology uses the role of computer vision to solve a problem with all the collected data by potentially preventing terrorist attacks, locating criminals and or missing people all stemming from face recognition platforms. The technology all though very unique and advanced is still far from perfect due to having produce far more false positives on non-white faces and it in addition as well has shown that it is actually not hard to fool facial recognition systems, there have even been researchers out there that have created anti-facial recognition glasses which can make the people that wear those glasses unrecognizable to the cameras. The advantages that facial recognition technology brings is most definitely vast where it can be implemented into restaurants and the waiters are able to service you by knowing what you look like (in need of assistance) there's also some automotive manufacturers that are implementing this kind of tech. In order to replace car keys. There are some concerns about whether all this being an invasion of privacy so there are many companies/places that are not full throttle yet with going all in with facial recognition.

As we progress more and more into the field of technology specifically in this instance facial recognition technology there will be more developments such as trying to make

everyone's lives more convenient by using your faceprint for business, financial institutions or hotels will be able to verify who you are without the physical use of ID. Facial recognition technology can without a doubt make life very easy for everyone to a certain metric and all though nice I believe that our privacy and safety is nicer and should be taken into more of an account. Humans by nature are lazy creatures so almost by default most will choose easy alternatives when it comes to whatever it may be in order to gain access to something to their convenience. The caveat to to benefits is also a lot and again needs to maintain the emphasis of privacy and safety along with ethical guidelines, so in all we will all have to wait and see and as information comes out I say the individual uses their critical thinking and asses as to how this will affect them in their daily lives and choose wisely within good faith of not only themselves but others as well.
